

L'EMILIA ROMAGNA VERSO ICAR 2013

Elevata prevalenza e severità dell'enfisema polmonare
associata con la morbosità cardiovascolare

Giovanni Guaraldi

The mosaic of aging

great variability
at all levels
of biological
organization:

- macromolecules
- organelles
- cells
- organs
- individuals
- populations

Expert Opin. Biol. Ther. (2008) 8(9):1393-1405

At an individual level the mosaic of aging
is described by frailty

The mosaic of aging

great variability
at all levels
of biological
organization:

- macromolecules
- organelles
- cells

- individuals
- populations

Expert Opin. Biol. Ther. (2008) 8(9):1393-1405

At an organ level the mosaic of aging is described by trajectories of function reserves

Smoke and premature aging lung

Chronic Obstructive Pulmonary Disease (COPD), is a common preventable and treatable disease, is characterized by persistent airflow limitation that is usually **progressive** and associated with an **enhanced chronic inflammatory** response in the airways and the lung to **noxious particles or gases**. **Exacerbations and comorbidities** contribute to the overall severity in individual patients.

Diagnosis requires spirometry:

$$\frac{\text{post-bronchodilator forced expiratory volume in one second } \mathbf{FEV1}}{\text{forced vital capacity } \mathbf{FVC}} \leq 0.7$$

Risk factors

- Smoking
- Socio-economic status
- Occupation
- Environmental pollution
- Recurrent bronchopulmonary infections

Natural history

of COPD is characterized by

- Acute exacerbations
- Chronic inflammation
- **Comorbidities such as chronic heart failure, -metabolic syndrome and others**

Peripheral lung inflammation may cause a spill over of cytokines into the systemic circulation

Healthy lung of a nonsmoker

Lung of a smoker with COPD
CD8+ T lymphocytes (in red)
infiltrate the airway wall

Peripheral lung inflammation may cause a “spill over” of cytokines into the systemic circulation, which may increase acute phase proteins (CRP, IL6, IL4) which may initiate and worsen comorbid conditions and lung cancer

Systemic effects and comorbidities of chronic obstructive pulmonary disease (COPD)

COPD at organ level: CT Imaging

Emphysema:

Abnormal, permanent enlargement of air spaces distal to the terminal bronchioles, accompanied by the destruction of their walls.

Bronchiolitis :

the airway becomes obstructed from swelling of the bronchiole walls

Both patterns can be present in COPD

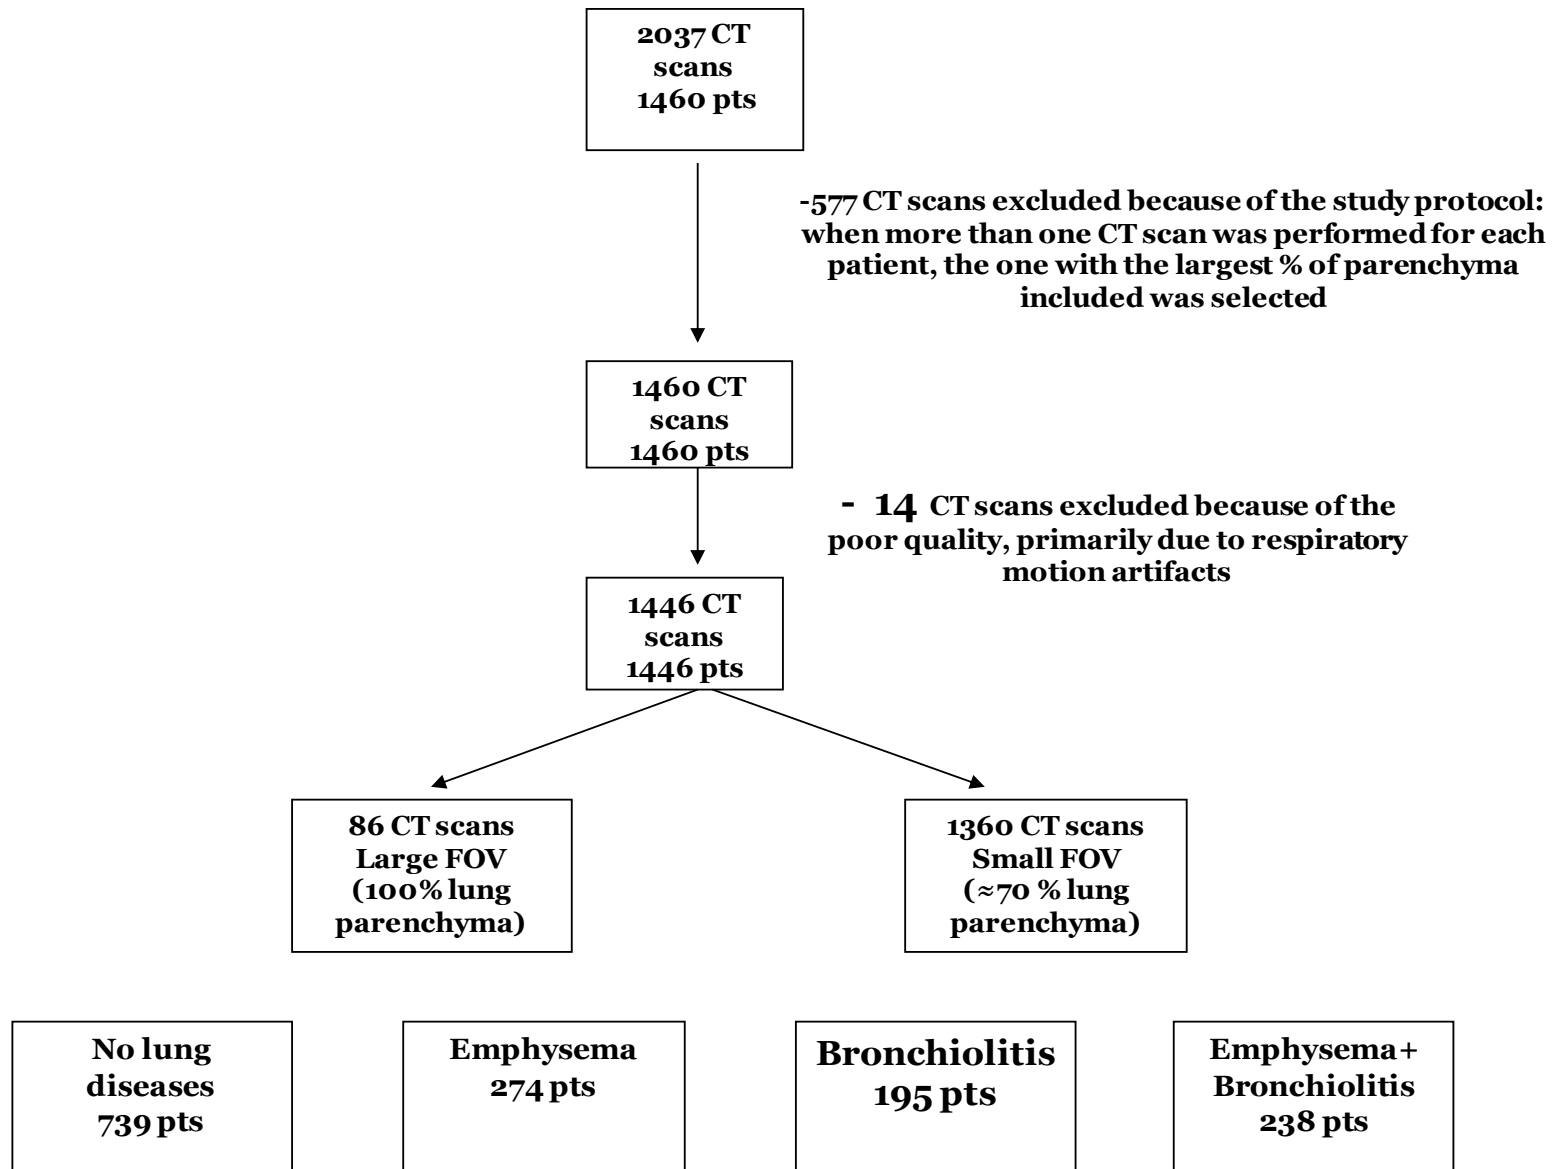

Objectives

1. To determine the prevalence of the two major morphologic COPD phenotypes, bronchiolitis and emphysema, using thoracic computed tomography (CT) imaging and to describe risk factors associated with these COPD phenotypes
2. To determine the association between emphysema severity and clinical and sub-clinical cardiovascular events (MACE)
3. To study natural history of emphysema in HIV and identify factors associated with emphysema progression (EP), assessed on sequential thoracic CT scans

Methods - 1

- Consecutive chest and abdominal CT of 1446 HIV patients were analyzed for pulmonary findings by two trained observers using a standardized protocol.
- Parenchymal abnormalities were evaluated with a continuous scoring system (with each of 6 lobes scored 0-4 to describe the burden of lung parenchyma showing bullae, centrilobular or paraseptal emphysema or centrilobular micronodules and patchy ground-glass opacity, with or without fine fibrosis).

Flow Diagram of Patient Selection

Clinical Characteristics of the 1,446 Consecutive Subjects With HIV Infection According to COPD Changes on CT Scans

Group	No lung disease	Bronchiolitis	Emphysema	Emphysema + Bronchiolitis	Global p value
No of Patients	739 (51%)	195 (13%)	274 (19%)	238 (16%)	<.0001
Age (years)	47.4±7.8	47.1±6.2	51.2±7.8 [*]	49.4±7.1 [†]	<.0001
Current Smokers	176 (24%)	110 (58%) [*]	95 (35%) ^{††}	177 (77%) ^{†††}	<.0001
> 10 cigs/day	76 (10%)	61 (31%) [*]	57 (21%) [*]	131 (55%) [*]	<.0001
Intravenous Drug Use	137 (19%)	63 (32%) [*]	98 (36%) [*]	105(44%) [*]	<.0001
HIV exposure (months)	192±76	212±76 [*]	211±68 [*]	217±74 [*]	<.0001
Nadir CD4 (cells/mm ³)	206±152	203±176	175±151 [*]	187±181	0.0309
Body mass index (kg/m ²)	24.1±3.9	23.0±3.4 [*]	23.8±3.7	22.8±3.3 [†]	<.0001
Visceral Adipose Tissue (cm ²)	132±75	115±58 [*]	147±92 ^{††}	125±70 [†]	<.0001
Prior Pneumonia	54 (8%)	25 (15%) [*]	41 (17%) [*]	39 (18%) [*]	0.0001
History of Asthma	5 (1%)	6 (4%)	1 (0%)	3 (1%)	0.0241
CRP (>1.1 mg/L)	322 (46%)	87 (48%)	120 (47%)	130 (59%) ^{††}	0.0138
White blood cell (cells/μL)	5872±1687	6095±1902	6302±1931 [*]	7498±2420 ^{†††}	<.0001
Regular Physical activity ^{††}	350 (49%)	72 (38%) [*]	115 (43%)	89 (39%) [*]	0.0088

Prevalence of CT lung abnormalities

Receiver operating characteristics curve to predict occurrence of COPD phenotypes on thoracic CT scans

Red line represents ROC of **cigarette smoking** (0.656; 95% CI, 0.631, 0.680)

Green line represents ROC of **cigarette smoking, peripheral WBC, history of intravenous drug use, and age** (0.730; 95% CI, 0.699 to 0.744).

Pulmonary Function Test Results Of 275 HIV Infected Subjects Stratified According To CT Based Lung Abnormalities

Group	No lung disease	Bronchiolitis	Emphysema	Emphysema + Bronchiolitis	Global p value
No of Patients	113 (41%)	48 (17%)	59 (21%)	55 (20%)	--

Major Adverse Cardiac Events	28(2.9%)	11(5.8%)	5(7.25%)	25(9.8)	<.0001

Prevalence of MACE (69 events) according to Emphysema severity score

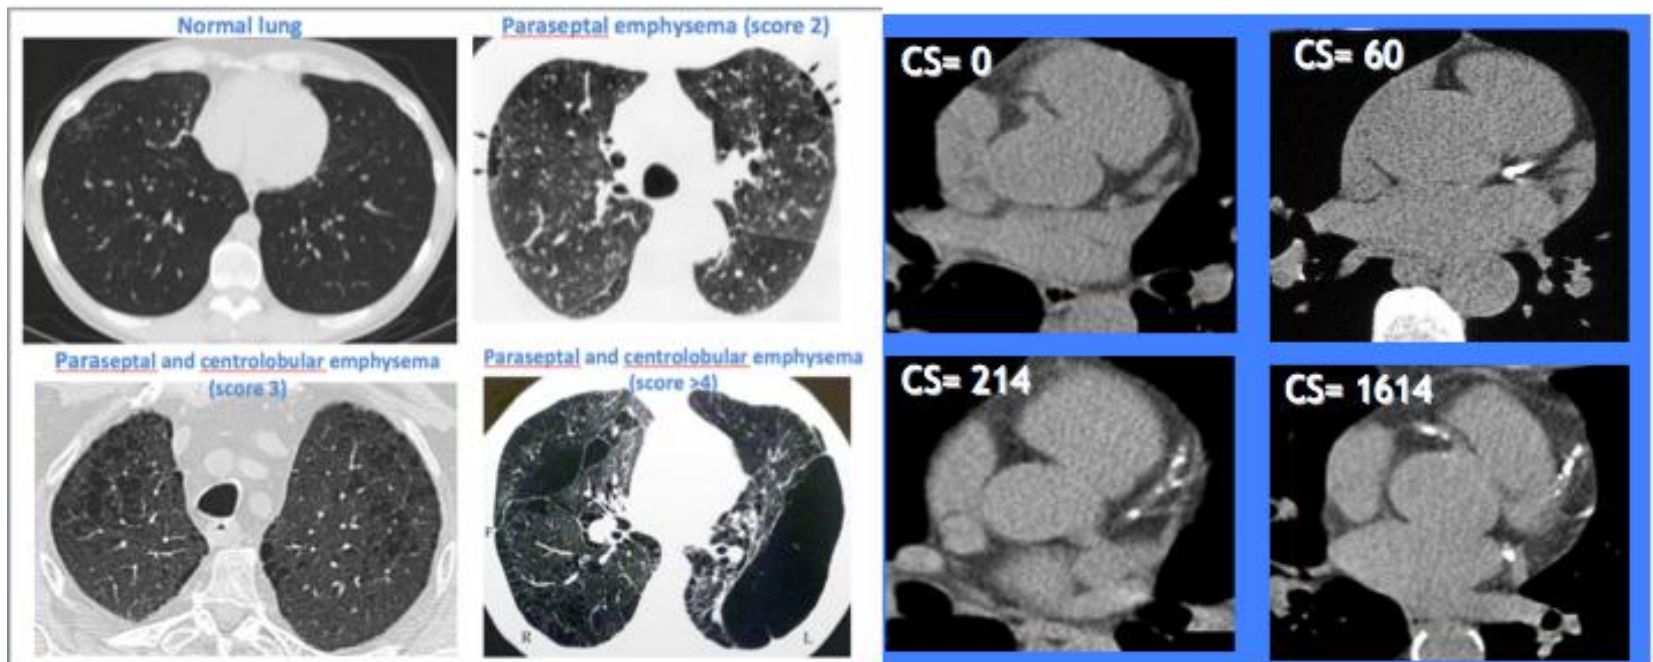

Logistic regression for MACE

Methods - 2

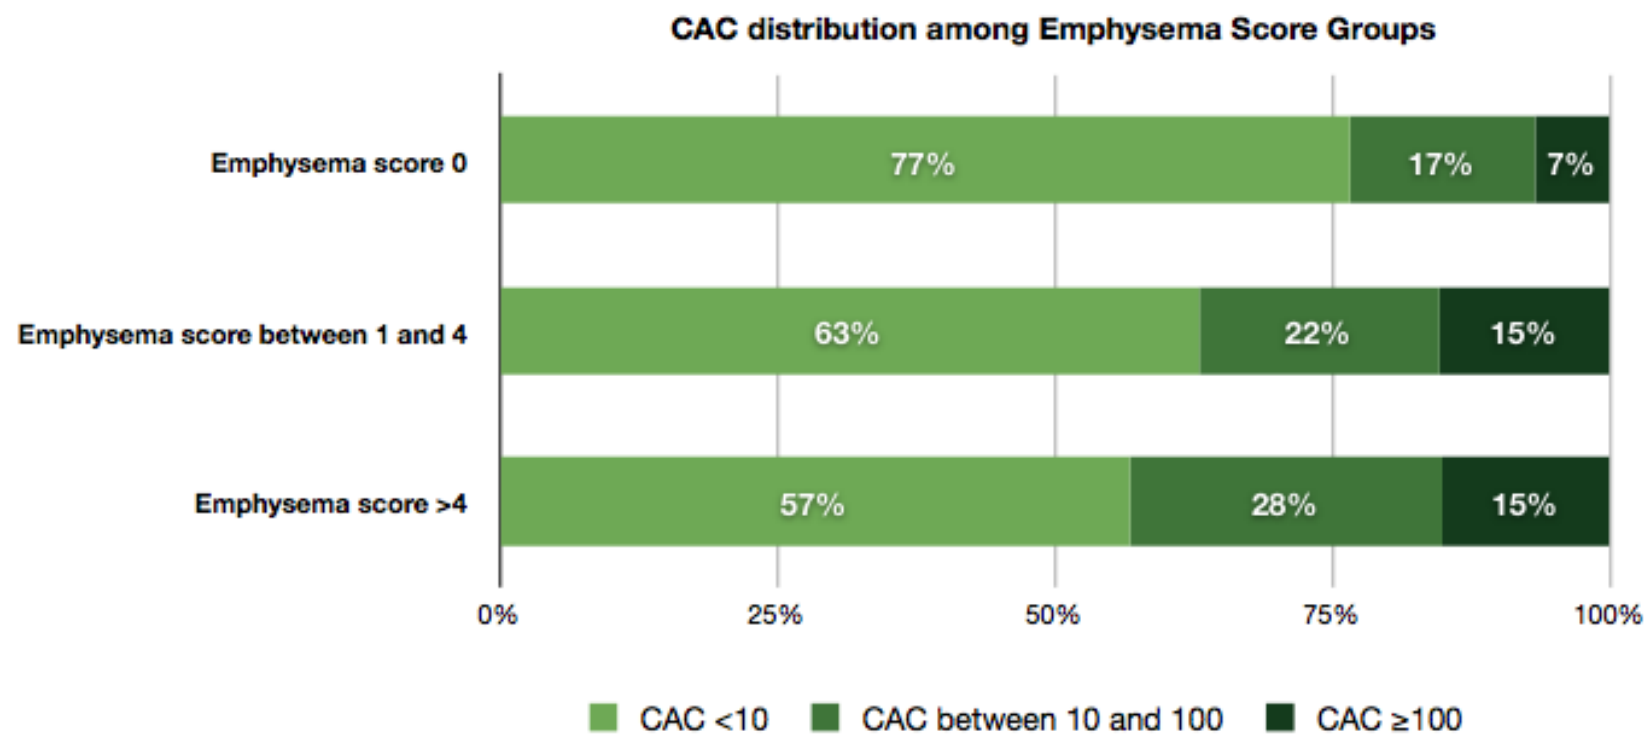

Emphysema score

Coronary Calcium Score
(CAC)

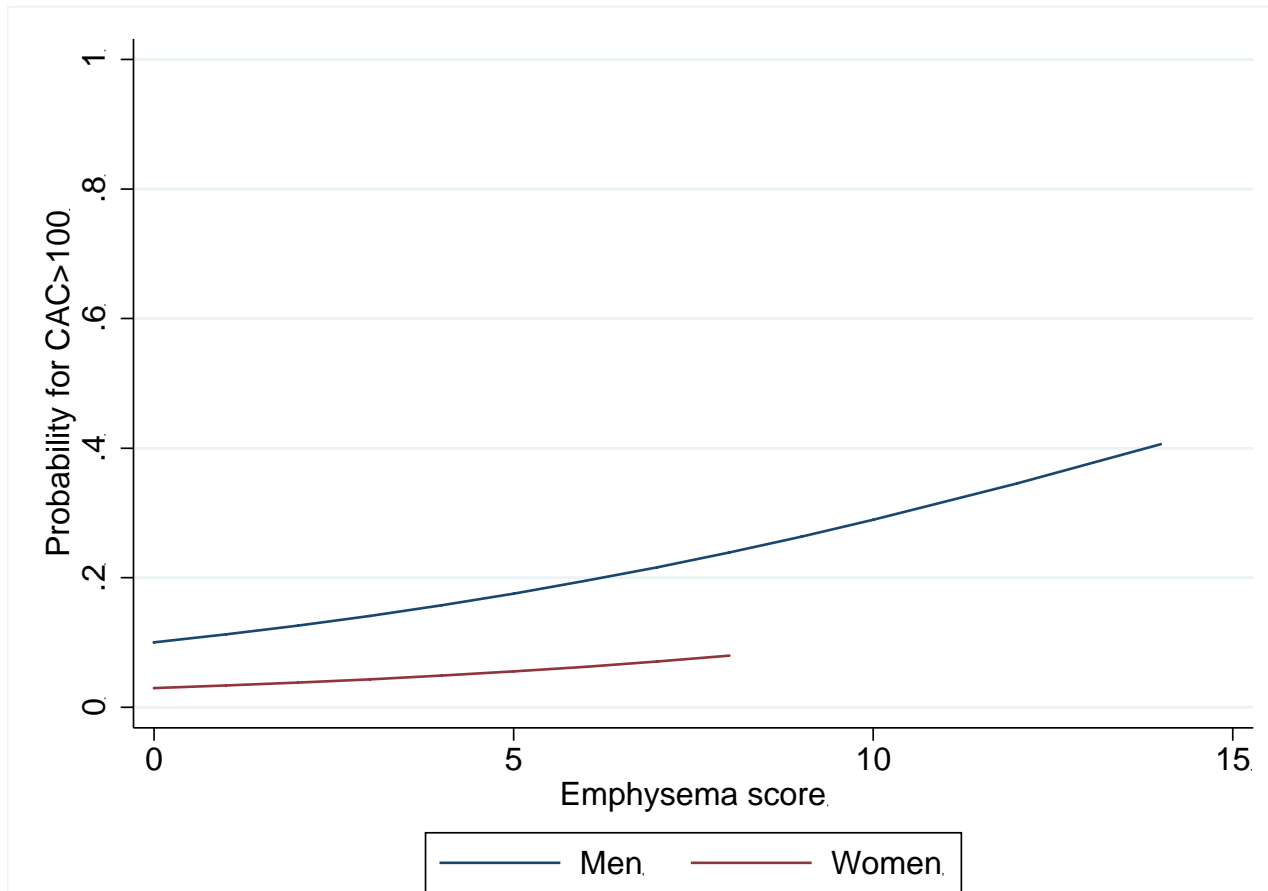

The CAC score was calculated according to the Agatston method

Asociación between CAC score according to Emphysema severity score

Emph. score 0 vs. 1-4 $p < 0.001$
Emph. score 0 vs. >4 $p < 0.001$
Emph. score 1-4 vs. >4 $p = 0.238$

Association between CAC and Emphysema score

Each point of emphysema score added a 10% risk of CAC > 100 (p=0.010)

Methods - 3

- Observational, prospective study of 448 consecutive HIV-infected antiretroviral therapy experienced patients (mean age 47,9 years, 24,1% females, 39,3% smokers) who underwent 2 sequential ECG-gated coronary artery calcium scoring CT scans.
- Images were reviewed by 3 radiologists by consensus to assess lung emphysema by using a visual semi-quantitative score (0 to 4) for each of 6 lobes.
- Emphysema progression was defined as an increase in emphysema score.

Emphysema progression and HIV exposure

Results

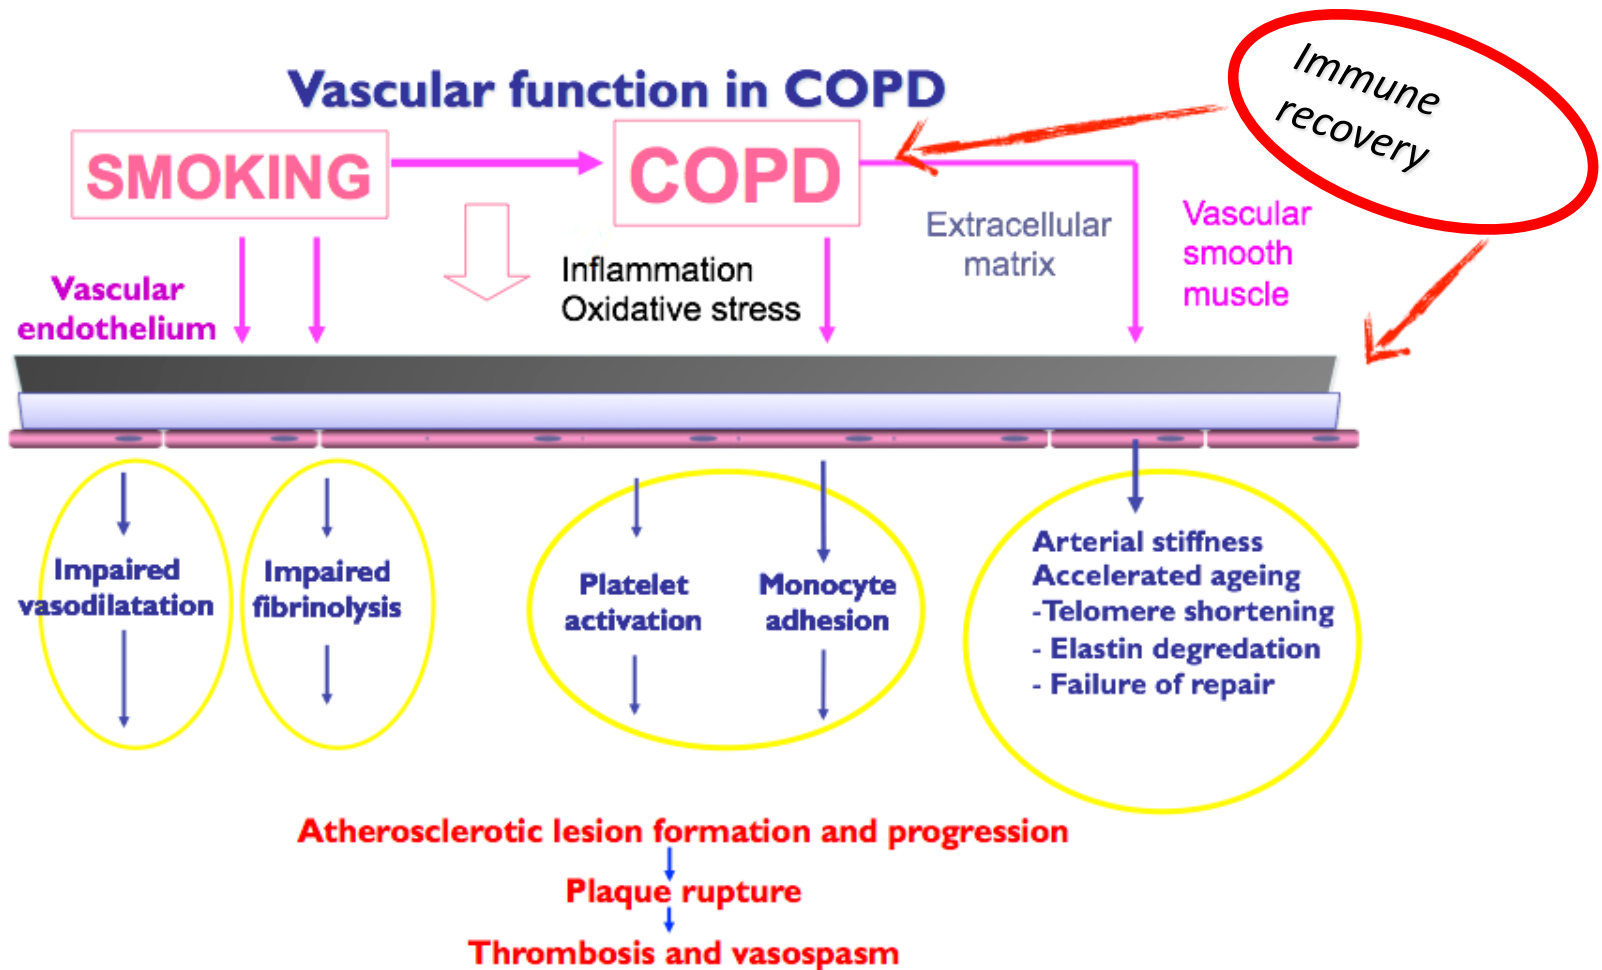

448 patients with repeated scans were included
18 patients a visual progression (frequency of progression 4.02%).

Multivariable analyses to identify predictors of emphysema progression

	OR	p-value
<10 cigarettes per day smoked	2,82	0,14
>10 cigarettes per day smoked	3,36	0,04
Time interval between the first and the last scan	1,51	0,03
HIV infection duration	1,01	0,01

Take home messages

1. Morphologically diagnosed COPD is present in 50%, of HIV infected patients who were not evaluated for respiratory complaints
2. This high disease burden and rapid progression suggest that smoke related lung disease in HIV could be included among the HIV Associated Non AIDS (HANA) conditions describing a premature aging lung process
3. COPD is an independent risk factor for clinical and subclinical cardiovascular disease
4. There is an urgent need to tackle the enormous burden of lung disease: COPD prevention, diagnosis and treatment must be developed in PLWH

HIV Associated Non AIDS (HANA) Conditions

Cardiovascular

Infectious and
Non infectious Cancers

Osteopenia
Osteoporosis

Liver diseases

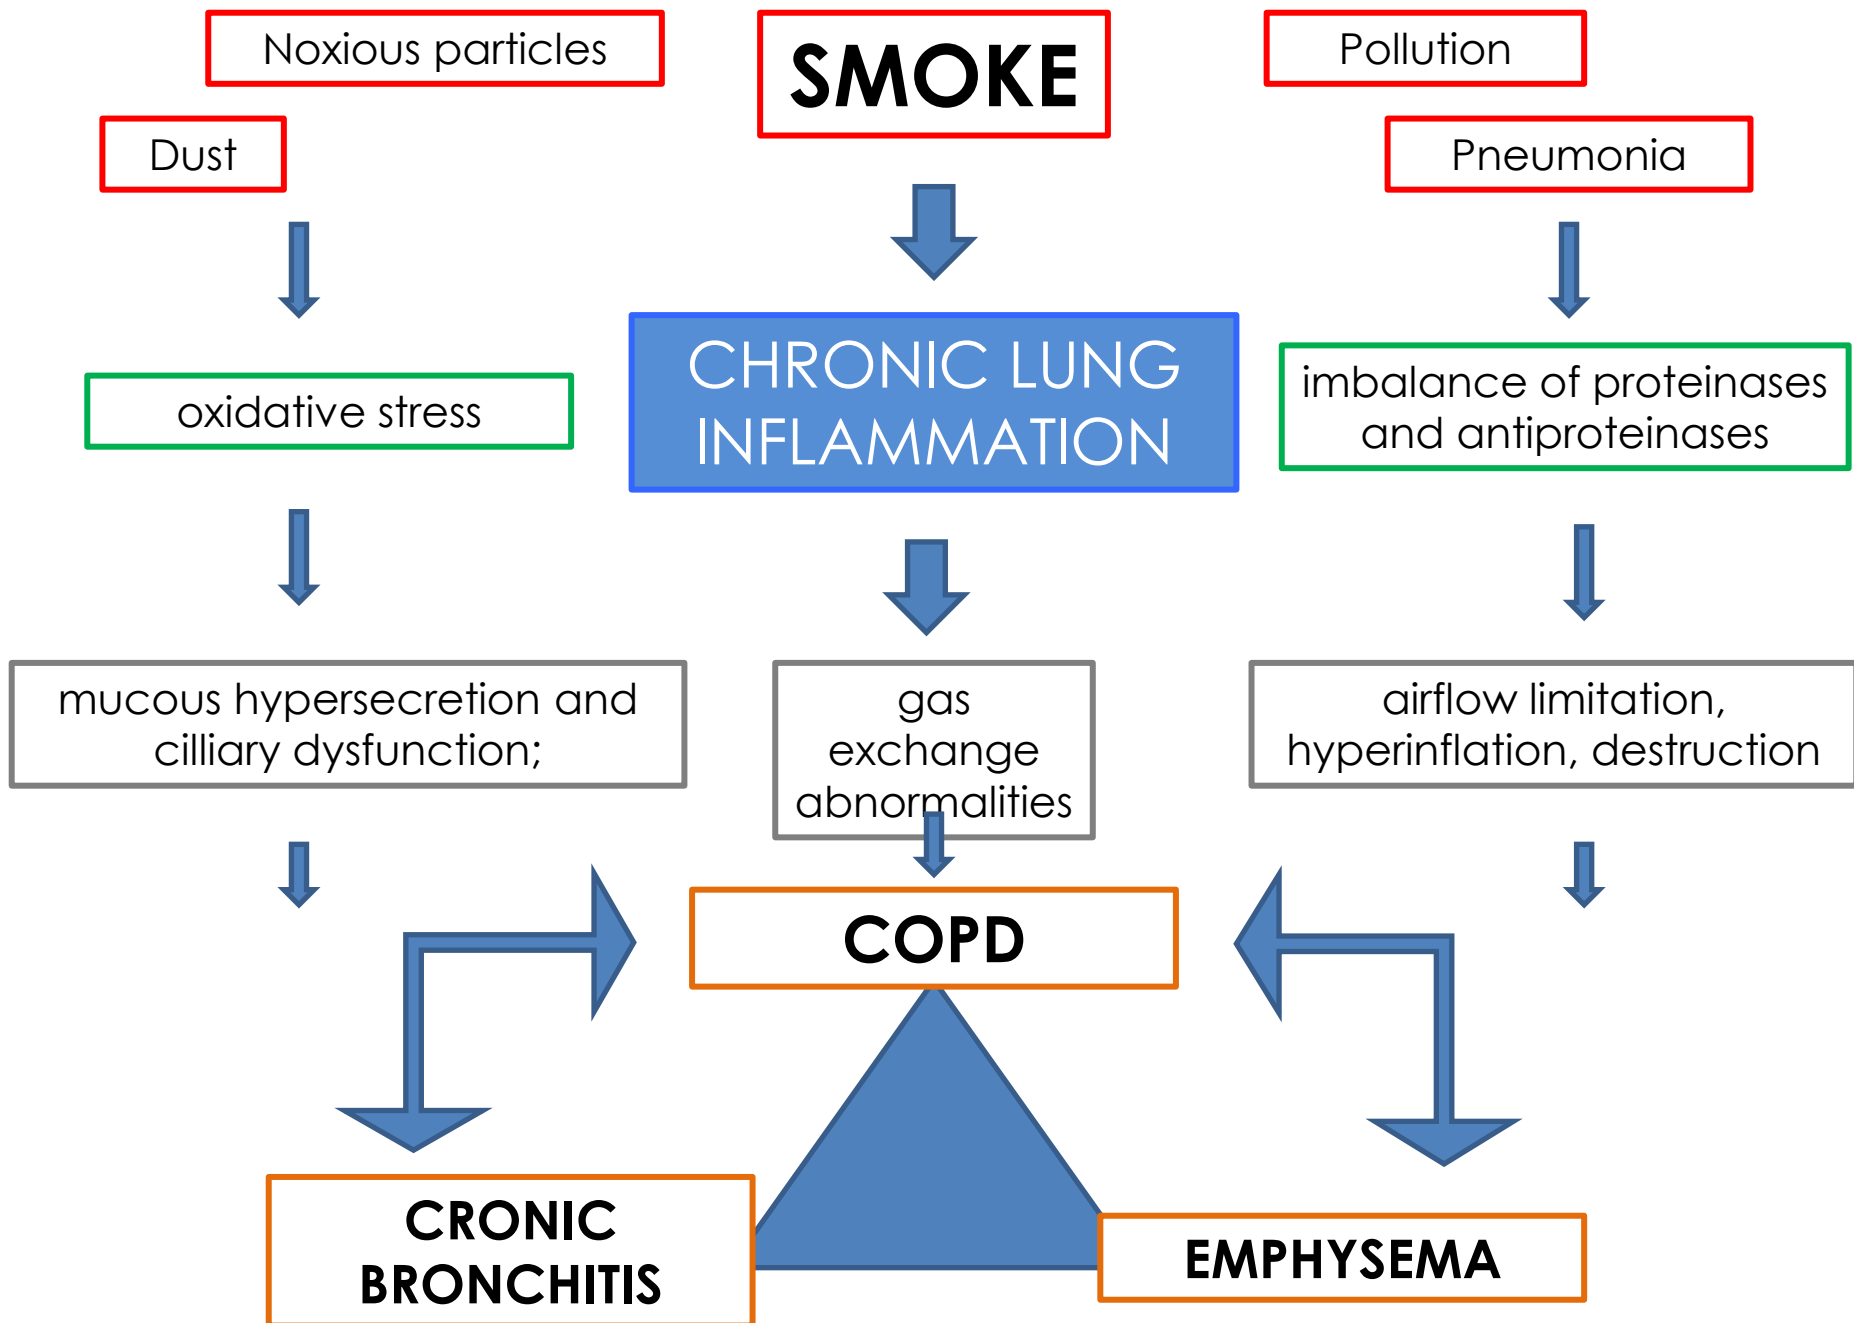

Renal Diseases

Neurocognitive
decline

- ✓ Are associated with advancing age and chronic inflammations
- ✓ After adjustment for established risk factors, association with HIV remains
 - Compare to demographically and behaviorally similar uninfected controls
 - Weaker (<2 fold) associations may be due to inadequate adjustment for risk factors

In the past anthropometric characteristics were used to differentiate emphysema patients from chronic bronchitis patients (1)

The '**pink puffer**' (emphysematous type) was characterized as being thin in appearance with frequent major weight loss

The '**blue bloater**' (chronic bronchitic type) was frequently obese with no marked weight loss, except occasionally in terminal stages

Now we know that COPD comprises pathological changes in four different compartments of the lungs (central airways, peripheral airways, lung parenchyma and pulmonary vasculature), which are variably present in individuals with the disease

Airway abnormalities and emphysema interact in a complex fashion in the development of airflow limitation in COPD

(1)Filley G F, et al. Chronic obstructive bronchopulmonary disease. 2. Oxygen transport in two clinical types. Am J Med 1968; 44:26-38
